## Overview

- Compartmental Models
- Cable theory
- Reduced models

# **Overview - compartmental models**

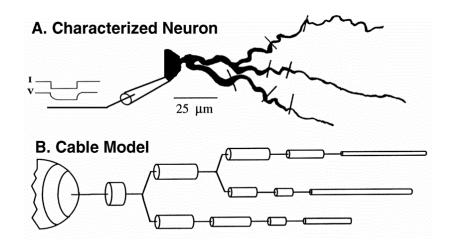

- Conductance-based models of neurons are composed of multiple spatial compartments
- Can reproduce the electrical behavior of the cell to a high level of accuracy
- Allow experimentation that may not be physically possible
- Allow investigation of any biophysically relevant parameter spaces
- Useful for testing theories and hypotheses
- Inform and guide experimental investigation

# **Dendritic facts**

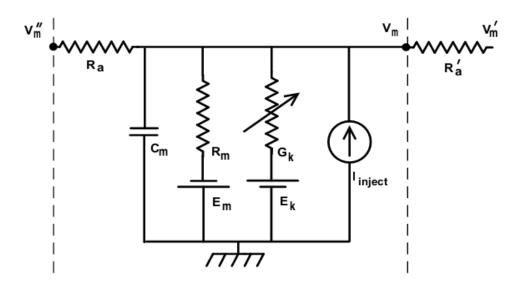

- Branching: Dendrites bifurcate repeatedly creating elaborate trees. Purkinje: ~400 terminal dendritic tips, motoneurons: ~10 tips. A type of neurons often has a unique branching pattern
- Diameters: Near the soma diameters can be a few  $\mu m.$  Diameter falls as they branch
- Dendrites are studded with dendritic spines (~0.1µm diameter, ~1µm length). In cortex, they receive the majority of excitatory input
- Dendritic tree length can vary greatly from 100-200 um to 1-2mm (motoneurons). Total dendritic tree length can exceed 1cm
- Majority of brain volume is occupied by dendrites
- Surface area of dendritic tree: 2000 750000 um<sup>2</sup>
- Volume of a dendritic tree: up to 30000 um<sup>3</sup>
- Synapses are not randomly distributed.
  - Inhibitory synapses are more proximal
  - Excitatory input sources may map to specific layers of a neuron
  - Excitatory inputs may be present in conjuction with inhibitory inputs away from the soma

# Equivalent Cylinder models

- The morphology of a neuron is broken down to a set of cylinders
- Cylinders are connected to each other through axial resistances
- Cylinders can have different lengths and diameters, and different, but uniform, membrane properties
- Every cylinder can be treated as an isopotential element

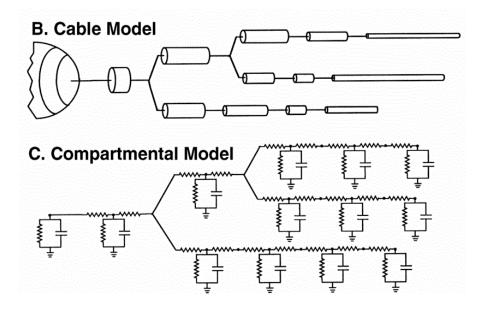

## **Equivalent Circuits**

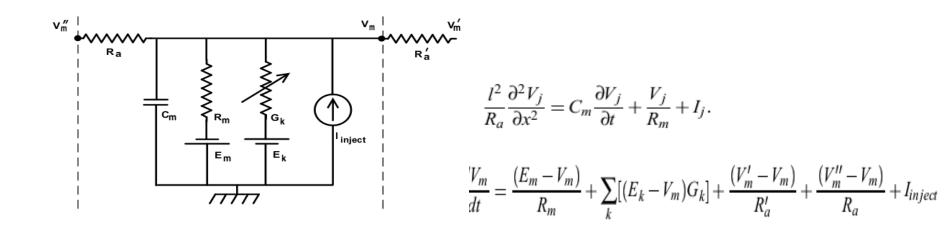

- In each cylinder voltage across the cell membrane v<sub>m</sub> depends on:
  - passive properties of the membrane (membrane capacitance  $c_m$  and membrane resistance  $R_m$ )
  - voltage-dependent currents (e.g.  $G_k$ )
  - and external current input

# Multi-compartmental models

- Compartments are connected with each other in series through the axial resistances (R<sub>a</sub>)
- Axial resistance models the movement of electrical charge when there is a voltage differential across successive compartments.
- The equivalent circuit consists of a capacitor that simulates the nonconducting bilipid cell membrane and a resistor as an analog of the conducting ionic channels on the membrane.

# **Cable theory**

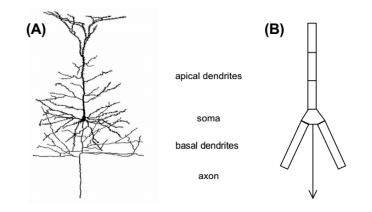

- Cable Theory solves the problem of the electric current flow in and out of a cylindrical core conductor
- The spatial spread of electrical signals over time is modeled with a nonlinear differential equation
- Neuronal simulator programs make use of a Taylor-series approximation of this equation

### Input resistance

- At a given point in the dendritic tree, R<sub>in</sub> is the ratio V<sub>0</sub>/I<sub>0</sub> when a steady current I<sub>0</sub> is applied to that point
- R<sub>in</sub> depends on the diameter of the cylinder
- A dendrite dp that bifurcates in two dendrites d1 and d2 behaves as a continuous cable for current that flows from parent to daughters if :
- Thus a branch point that obeys this rule is equivalent to a uniform cylinder
- Many types of dendritic trees obey this rule such as a-motoneurons, but others don't (cortical, hippocampal)
- This concept has been extended to dendritic trees (Rall 1959,1989)

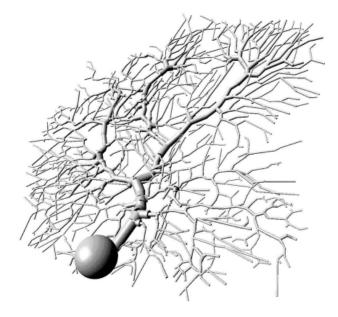

$$R_{in}=(1/\pi)d^{-3/2}\sqrt{R_MR_A}.$$

$$d_p^{3/2} = d_1^{3/2} + d_2^{3/2}.$$

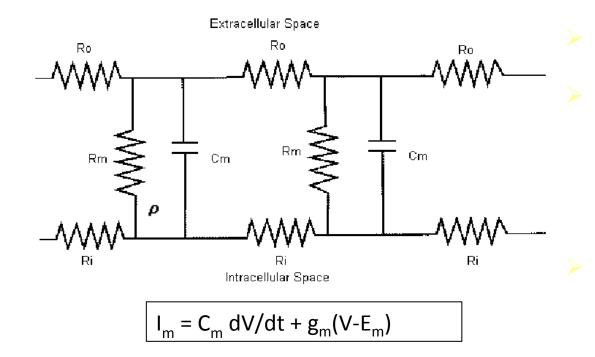

## Modeling compartmental neurons

- Thousands of compartments may be used to simulate extended and complex dendritic trees such as the Purkinje cell
- Most models use 3Dreconstructions based on light microscopy images of biocytin-filled cells using specialized software (Neurolucida)
- Most models employ simplifications to reduce the number of simulated cylinders
- Reducing a number of passive dendritic trees to an equivalent passive cable is straightforward
- For active dendrites this is not possible due to the different local impedance of the reduced dendrite.
- Synaptic spines are often reduced to single points

DeSchutter 1994

### Passive membrane properties

 $\lambda$  = distance at which V=V\_o\*1/e = 0.37 V\_o

 $\lambda = R_m/(R_i+R_o)$  and since  $R_o$  is small  $\lambda = R_m/R_i$ (LENGTH or SPACE CONSTANT)  $t = R_mC_m$ (TIME CONSTANT) R<sub>o</sub> = vanishingly small

R<sub>i</sub> = Dependent on cytoplasm resistivity and crossectional area:

> R<sub>i</sub> = (L/A)\**r* where *r* = cytoplasmic resisivity

R<sub>m</sub> = Dependent on specific membrane resistivity/cm<sup>2</sup>

Voltage attenuation with conduction:

Along distance

$$V = V_0 *_e^{-x/\lambda}$$

b) With time

$$\mathbf{V} = \mathbf{V}\mathbf{o} \star \mathbf{e}^{-\mathbf{t}/\mathbf{\tau}}$$

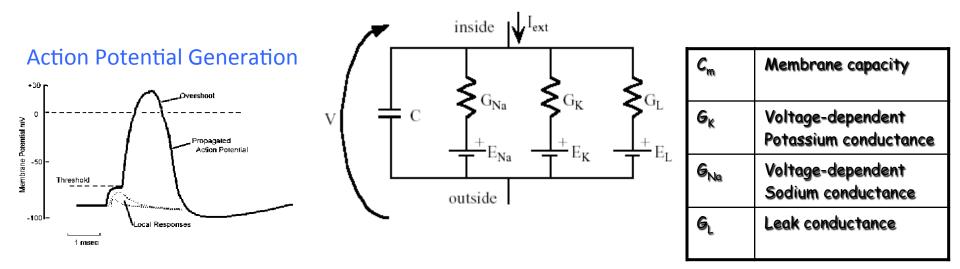

### From passive to active neurons

For "short" cells passive propagation suffices to signal a potential change from one end to the other.

If the axon is long, this is inadequate since changes at one end would decay away almost completely before reaching the other end.

If the change in potential difference is large enough, then in a cylindrical configuration such as the axon, a pulse can actively propagate at full amplitude. The Hodgkin-Huxley Equations (1952)

### Active membrane properties

Hodgkin and Huxley (1952): they did a series of experiments using the giant axon of the squid to characterize the mechanisms of action potential generation

$$I_{ext} = C_m dV/dt + G_L(V-E_L) + G_K n^4(V-E_K) + G_{Na}m^3h(V-E_{Na})$$

In reality, many more mechanisms are responsible for membrane potential changes, like Ca<sup>++</sup> channels ( $I_{caT}$ ,  $I_{caR}$ ,  $I_{caL}$ ), other types of K<sup>+</sup> channels ( $I_A$ ,  $I_m$ ,  $I_{sAHP}$ ,  $I_{mAHP}$ ) and Na<sup>+</sup> channels ( $I_{Nap}$ ), pumping and buffering mechanisms e.t.c

Voltage-gated ion channels are sometimes open, sometimes closed, depending on the membrane potential and/or other factors.

Passive Ion Channels: Active Ion Channels:

Probability that ion channel is open

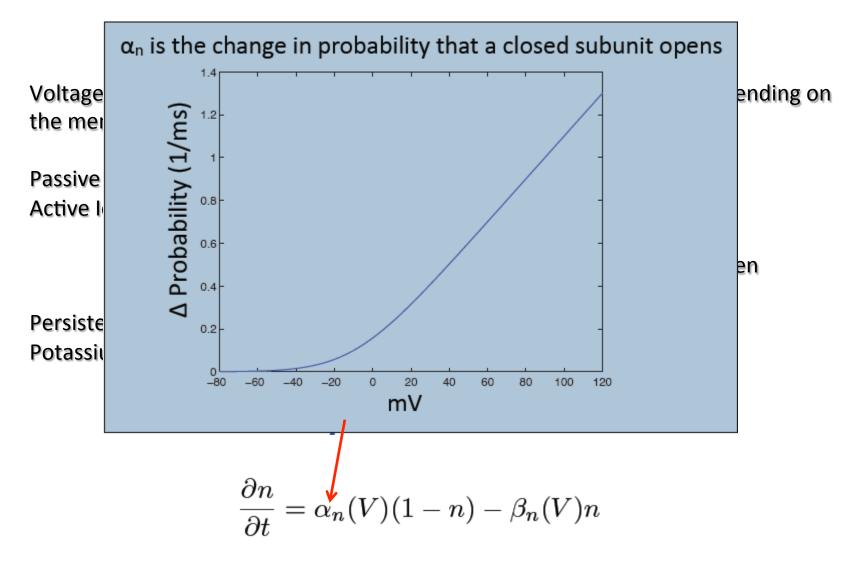

Persistent Channels (K+)

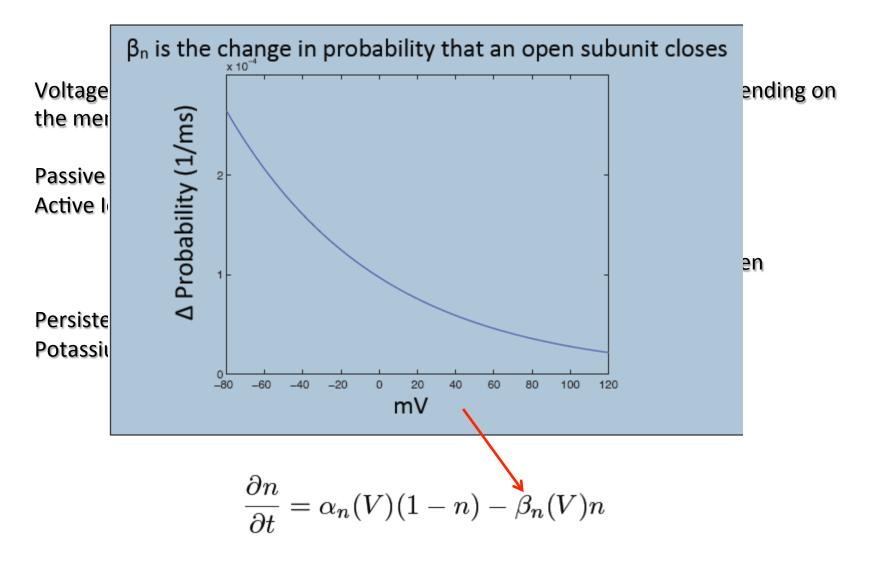

Potassium channels are only open when all 4 subunits are open.

n is the probability of the subunit being open.

$$P_K = n^4$$

$$\frac{\partial n}{\partial t} = \alpha_n(V)(1-n) - \beta_n(V)n$$

Voltage-gated ion channels are sometimes open, sometimes closed, depending on the membrane potential and/or other factors.

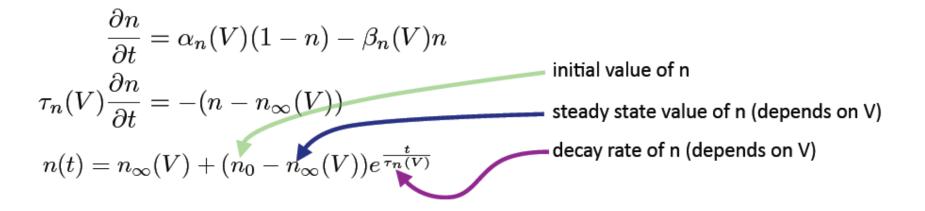

Passive Ion Channels: Active Ion Channels:

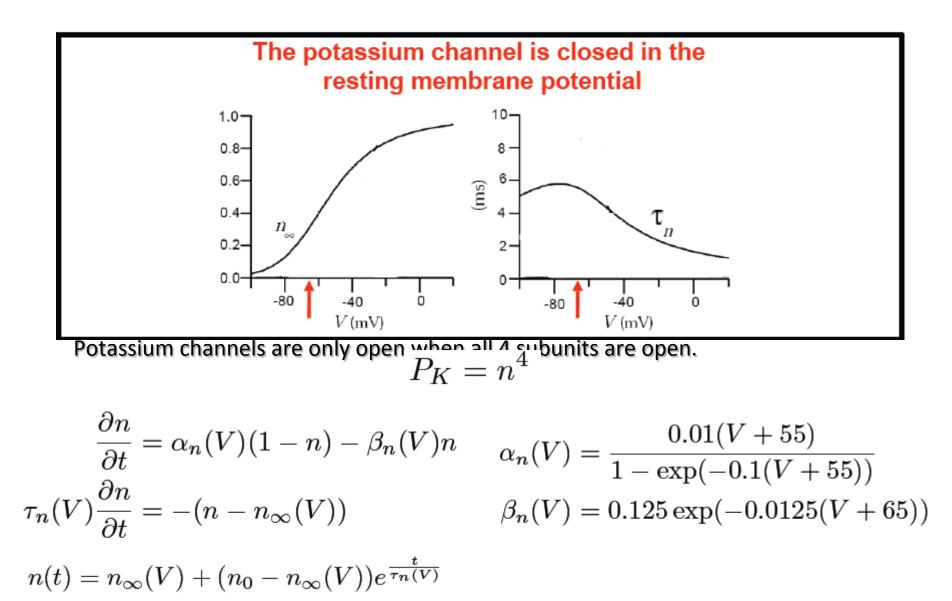

Probability that ion channel is open

Persistent Channels (K+)

Potassium channels are only open when all 4 gubunits are open.

$$P_K = n^4$$

### Active ion channels

Transient Sodium channels (Na+)

Transient sodium channels are only open when all 3 activation units (m) and the inactivation unit (h) are open.

$$P_{Na} = m^3 h$$

$$\frac{\partial m}{\partial t} = \alpha_m(V)(1-m) - \beta_m(V)m$$
$$\frac{\partial h}{\partial t} = \alpha_h(V)(1-h) - \beta_h(V)h$$

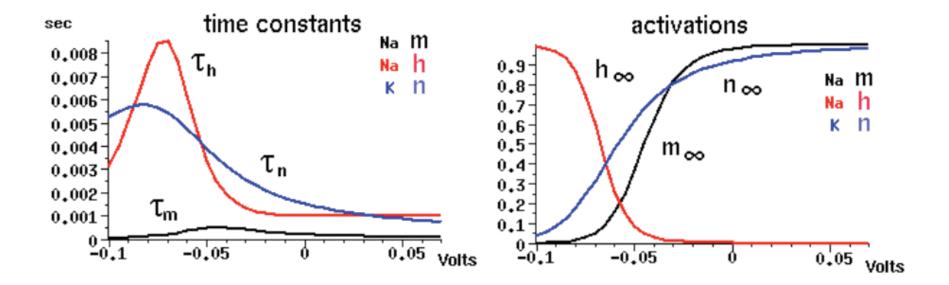

$$\alpha_m(V) = \frac{0.1(V+40)}{1-\exp(-0.1(V+40))}$$
  
$$\beta_m(V) = 4\exp(-0.0556(V+65))$$

$$\alpha_h(V) = 0.07 \exp(-0.05(V+65))$$
$$\beta_h(V) = \frac{1}{1 + \exp(-0.1(V+35))}$$

### **Action potentials**

Na<sup>+</sup> activation units  $\tau_m(V)$ Na<sup>+</sup> inactivation units  $\tau_h(V)$ K<sup>+</sup> activation units  $\tau_n(V)$ 

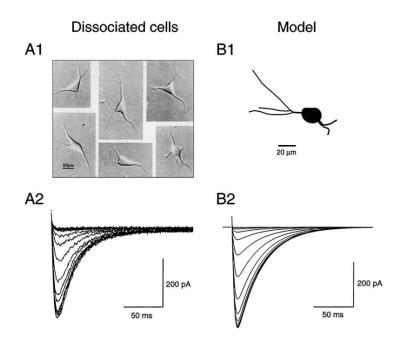

$$\tau_m(V)\frac{\partial m}{\partial t} = -(m - m_\infty(V))$$
$$\tau_h(V)\frac{\partial h}{\partial t} = -(h - h_\infty(V))$$
$$\tau_n(V)\frac{\partial n}{\partial t} = -(n - n_\infty(V))$$

Larger  $\tau$  means slower channel response to voltage

# **Model Calibration**

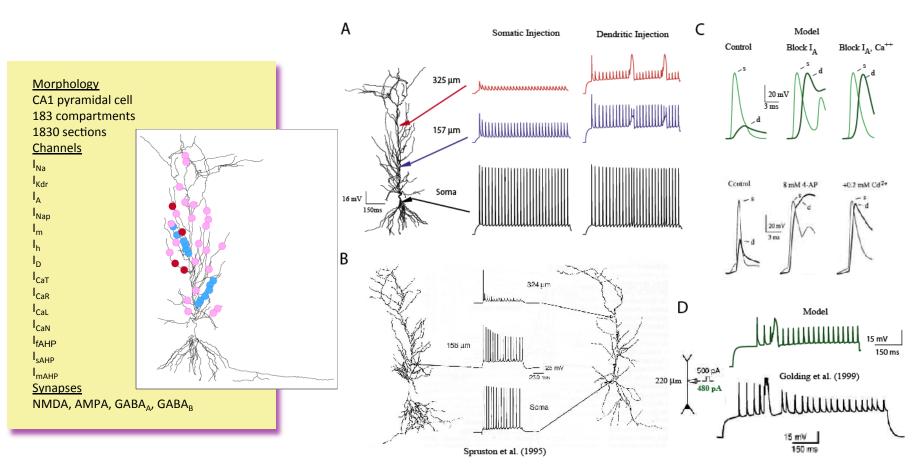

- In order for a model neuron to perform as closely as possible to a real neuron, it needs to be constrained against all the available experimental data for the specific neuron type
- Calibration requires careful examination of the relevant literature, experimental evidence, as well as the intuition of the experimenter
- Voltage responses of the cell to *in vitro* current stimulation with varying simple currents can be used as benchmark for the model
- In order to constrain kinetic models, whole cell recordings are often used, attempting to match the model response to the recorded waveforms

Destexhe 1998

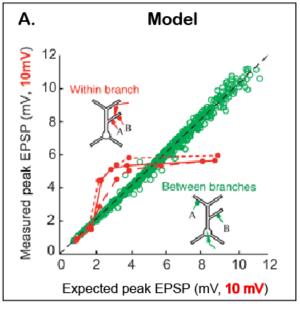

**Examples of compartmental modeling studies from our lab** 

# Single neuron: dendritic integration in a CA1 pyramidal cell model

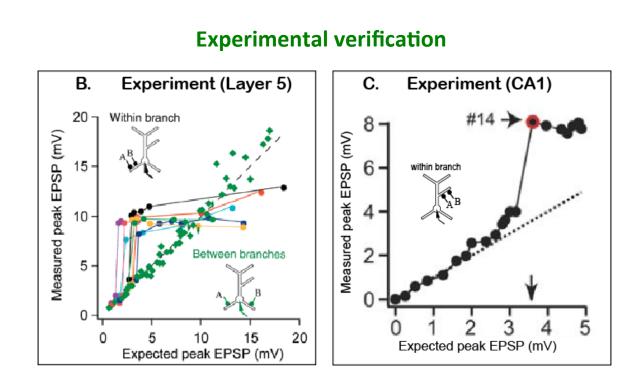

The model was heavily validated using multiple experimental data from in vitro studies

### Prediction: dendrites integrate inputs like semiindependent sigmoidal units

Poirazi et al, Neuron, 2003a

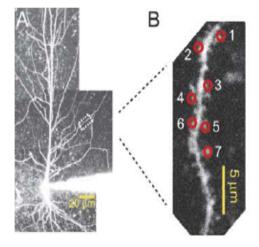

B. Polsky et al, Nat. Neuro., 2004

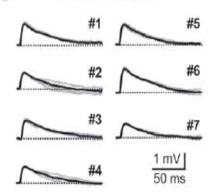

C. Losonczy & Magee, Neuron, 2006

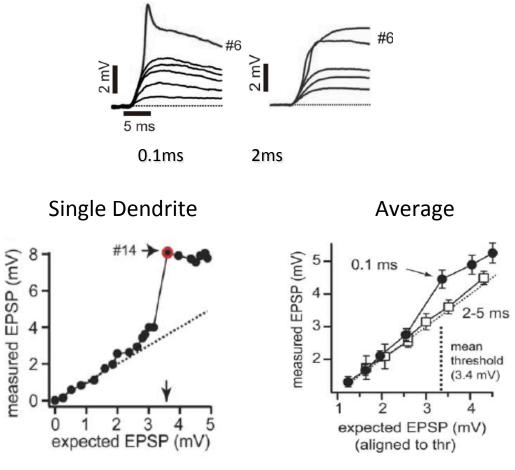

### **Coincidence detection in CA1 obliques**

Synchronous stimulation  $\rightarrow$  dendritic spikes

Multisite two-photon glutamate uncaging. Single pulse stimulation.

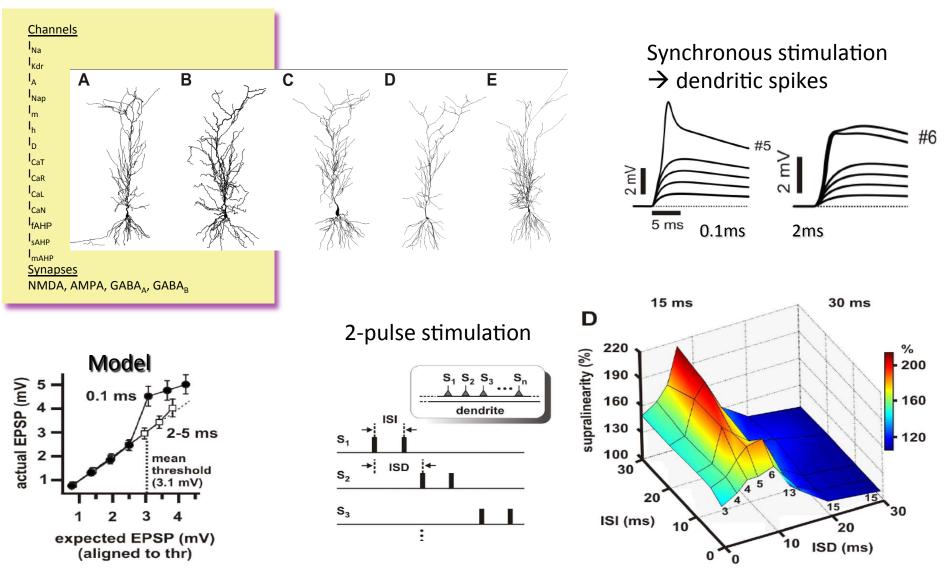

CA1 obliques detect (amplify) only synchronous inputs

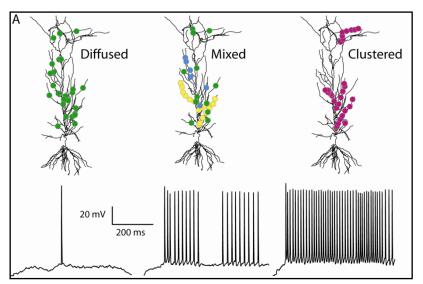

Losonczy & Magee, Neuron, 2006 also see Ariav et al, J. Neurosc., 2003

# Prediction: non-synchronous and bursty can also be detected

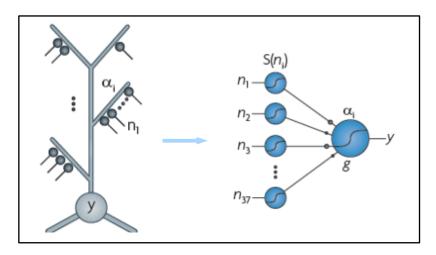

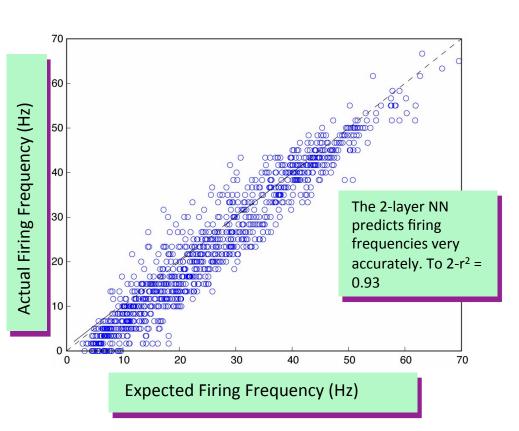

Gomez et al, Front. Comp. Neurosc., 2011

### Prediction: CA1 pyramidal neuron as a 2-layer ANN

Measure firing rate in response to > 1000 different synaptic arrangements

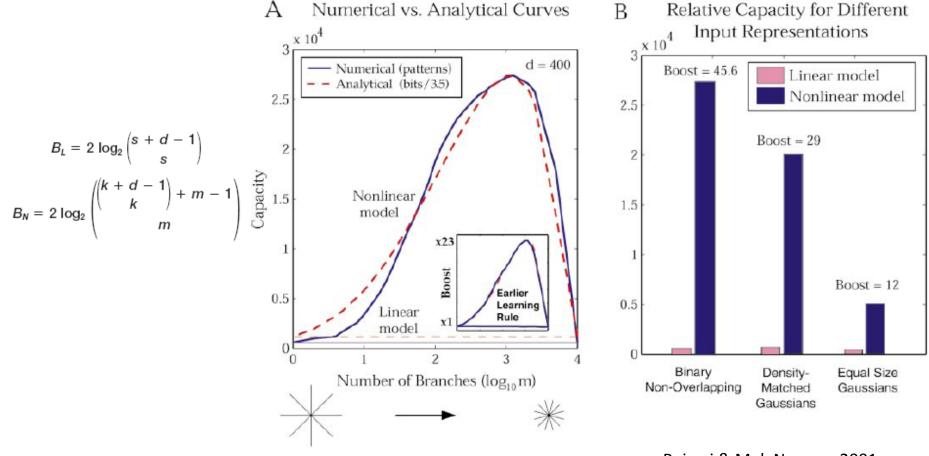

A simple 2-layer ANN abstraction predicts The average firing frequency of the model to > 1000 inputs patterns with high accuracy.

Poirazi et al, Neuron, 2003b

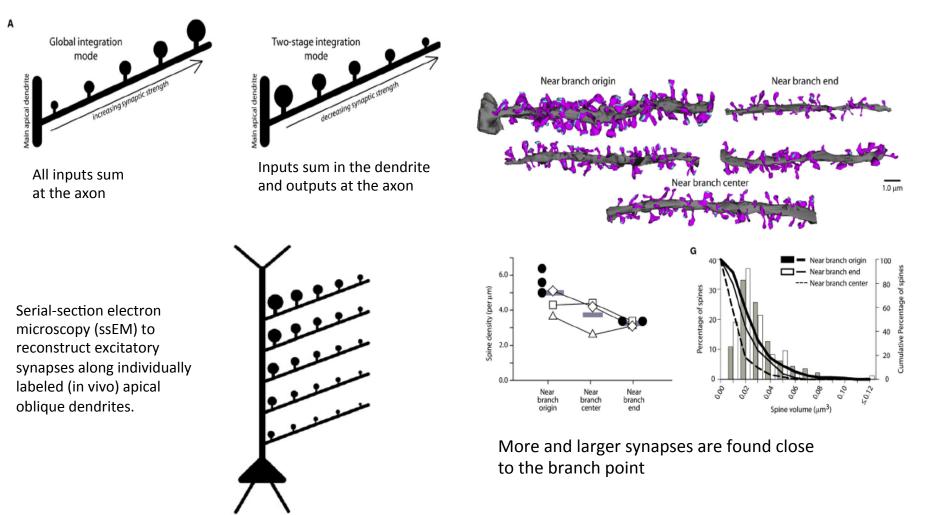

### What is the benefit of having such neurons?

Poirazi & Mel, Neuron, 2001.

#### Nonlinear neurons can learn one order of magnitude (45 times) more memories than linear neurons.

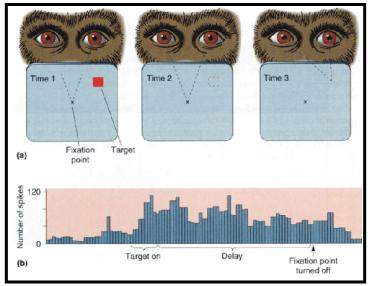

### Experimental support for 2-stage integration

Proposed 2-stage model

Katz et al, Neuron, 2009

### Simulating working memory in the PFC

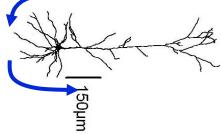

Goldman-Rakic, 1992

#### Synaptic mechanisms

Intrinsic mechanisms

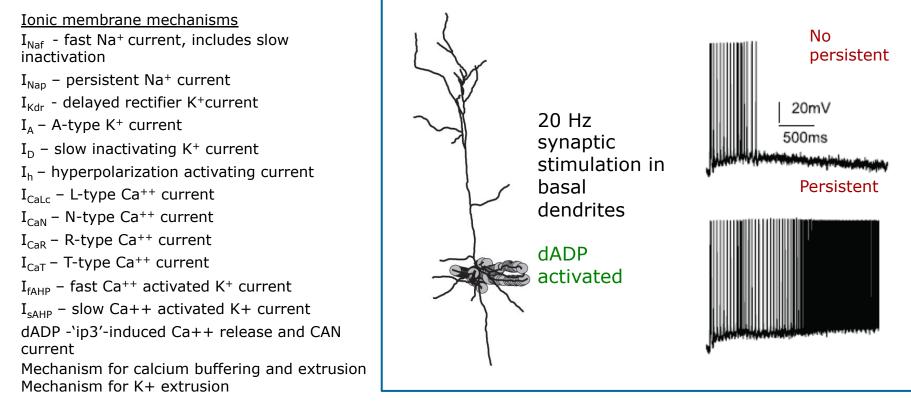

Egorov et al, 2002

# Single neuron: L5 PFC pyramidal neuron model expressing Persistent Activity

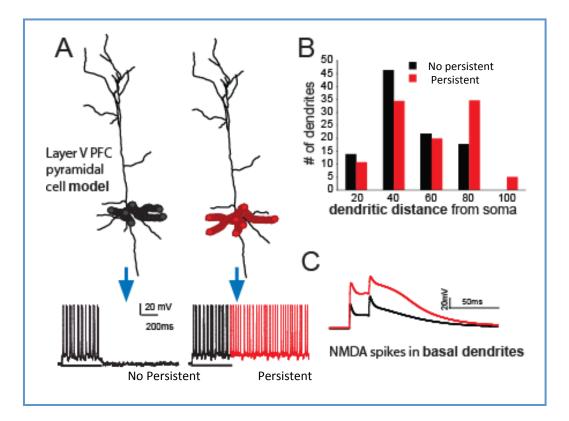

#### Kiki Sidiropoulou

 $\frac{Synaptic Mechanisms}{NMDA, AMPA, GABA_A, GABA_B}$ 

Persistent activity is induced with a probability, depending on the spatial arrangement of synaptic inputs onto basal dendrites.

### Prediction: Persistent activity emerges when inputs are located in thin, terminal tips

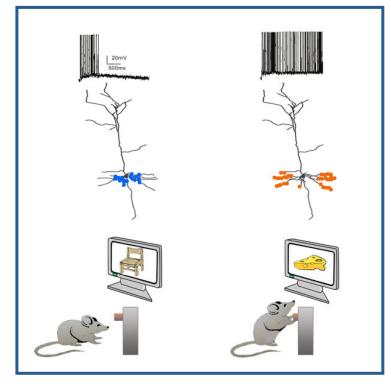

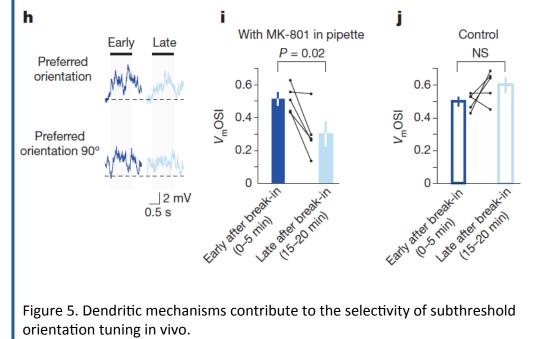

Persistent activity trials are associated with inputs located in <u>more distal dendrites</u> and <u>larger NMDA spikes</u>.

Since NMDA conductance is the same, <u>dendritic morphology</u> underlies differences in NMDA spikes.

Sidiropoulou and Poirazi, PloS Comp. Biol., 2012

# Prediction & support: a dendritic mechanism for input specificity

A dendritic mechanism for input specific persistent firing, based on NMDA spikes

NMDA-dependent dendritic spikes increase the selectivity of neuronal responses to the orientation of a visual stimulus (orientation tuning)

Nassi Papoutsi

### Microcircuit level: L5 PFC module expressing Persistent Activity

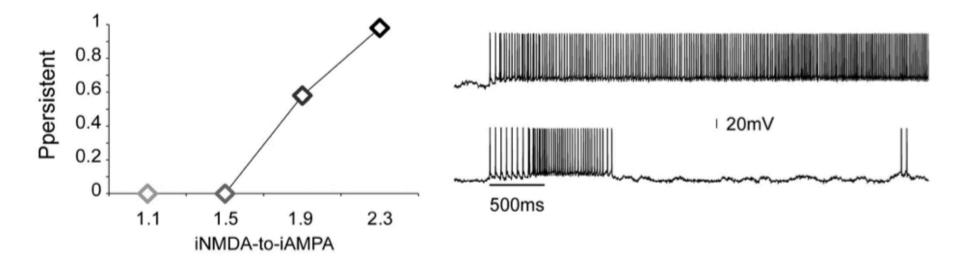

- Pyramidal neurons contain all mechanisms in the detailed single cell model
- Connectivity based on experimental anatomical and electrophysiological data
- Latencies of connections drawn from Gaussian distributions, in accordance with experimental data
- Membrane noise due to stochasticity in ionic currents (Poisson distribution)
- Background synaptic activity

	Type of connection	Location	# of synapses	Reference
	Thalamocortical (incoming)	Proximal dendrite	90	(Kuroda M et al., 1998)
	Pyramidal recurrent	Basal dendrite	5	(Markram et al., 1997)
	Pyramidal-to-interneuron	Soma	2	(Buhl et al., 1997)
	Autapses in pyramidal neurons	Basal dendrite	1	(Lübke et al., 1996)
	Interneuron-to-pyramidal	Soma	4	(Gabor Tamás et al., 1997)
	Autapses in the interneuron	Soma	12 synaptic contacts	(Bacci et al., 2003; G Tamás et
			producing ~350pA	al., 1997)

Connectivity properties

#### L5 PFC microcircuit

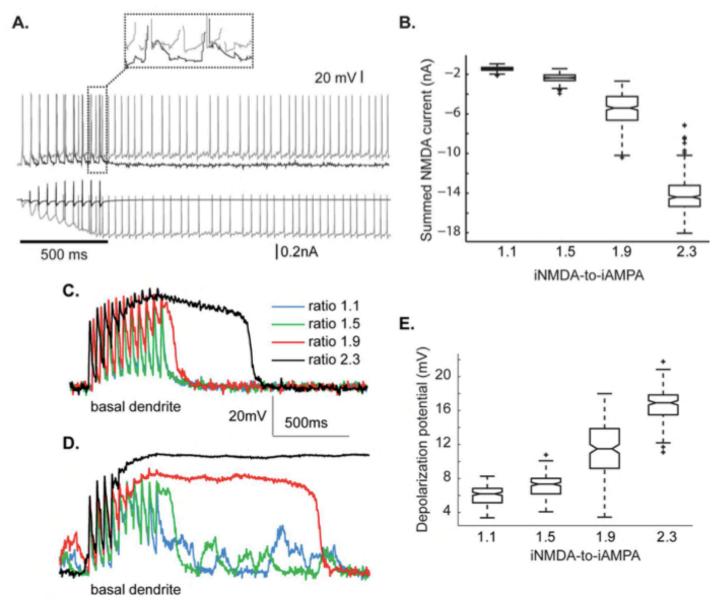

# Persistent activity is induced in the microcircuit given sufficient NMDA current

NMDA conductance is necessary for persistent activity induction. Blockade of NMDA receptors eliminates persistent activity.

Papoutsi et al, PloS Comp. Biol., 2014

# Prediction: dendritic NMDA spikes are critical for persistent activity induction

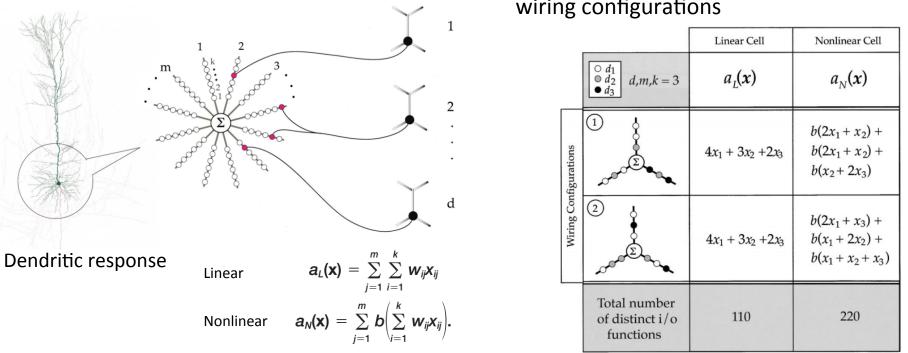

## Summary

- Prediction: dendrites of CA1 pyramidal cells integrate inputs as semiindependent sigmoidal units. Verified
- Prediction: CA1 neurons act as 2-stage integrators. Evidence in favor
- Prediction: dendritic synapse location may serve as a mechanism for stimulus specificity via the induction of dendritic spikes. Supported experimentally in other neurons
- Prediction: dendritic NMDA spikes play a permissive role for the induction of persistent activity. Pending

## Simplified dendritic models

- Why simplify dendrites?
  - More compact mathematical formulation
  - Easier to analyze theoretically and analytically
  - Make it easier to simulate neurons in large numbers
  - Comparison with the learning models of Artificial Neural Networks

### Simplified model of a neuron with linear or sigmoidal dendrites

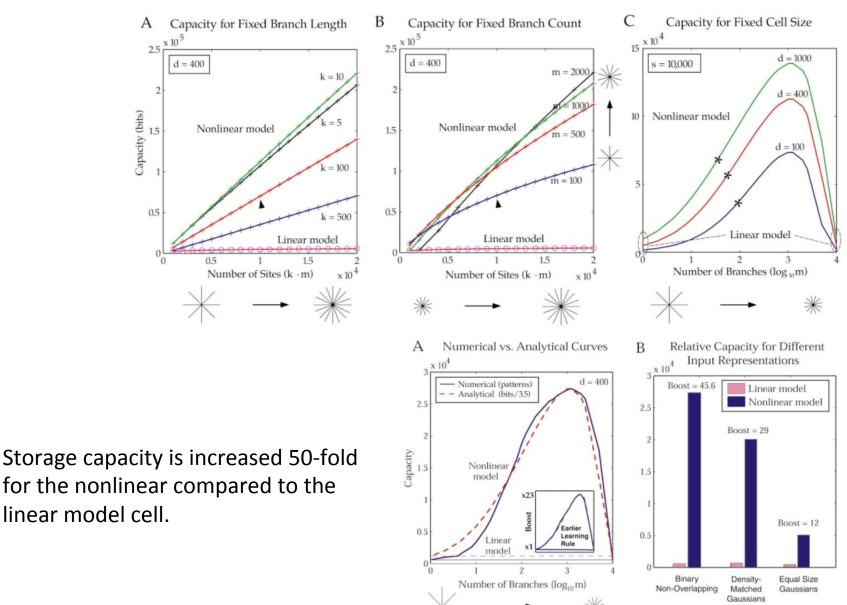

A nonlinear cell can distinguish between wiring configurations

Cell output = excitatory - inhibitory  $y(x) = sgn [a^{+}(x) - a^{-}(x)]$ 

- Cell is modeled as a set of m identical branches connected to a soma, where each branch contains k excitatory synaptic contacts.
- Each synapse is driven by one of d input lines and is given a small integervalued weight.

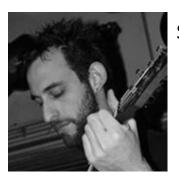

Poirazi, Neuron 2001

### Sigmoidal dendrites increase storage capacity

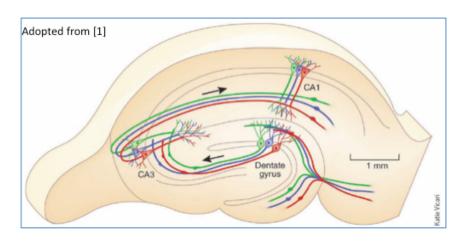

Poirazi, Neuron 2001

**Spiros Chavlis** 

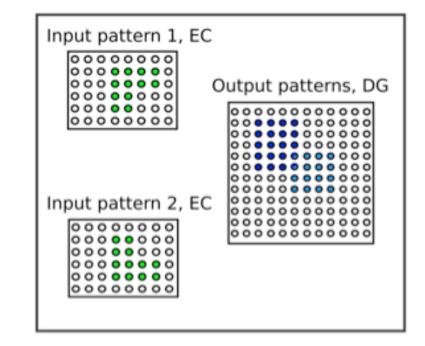

### Network level: role of DG dendrites in Pattern Separation

 Pattern separation: computational task which transforms <u>overlapping</u> (similar) input to <u>non-overlapping</u> representations

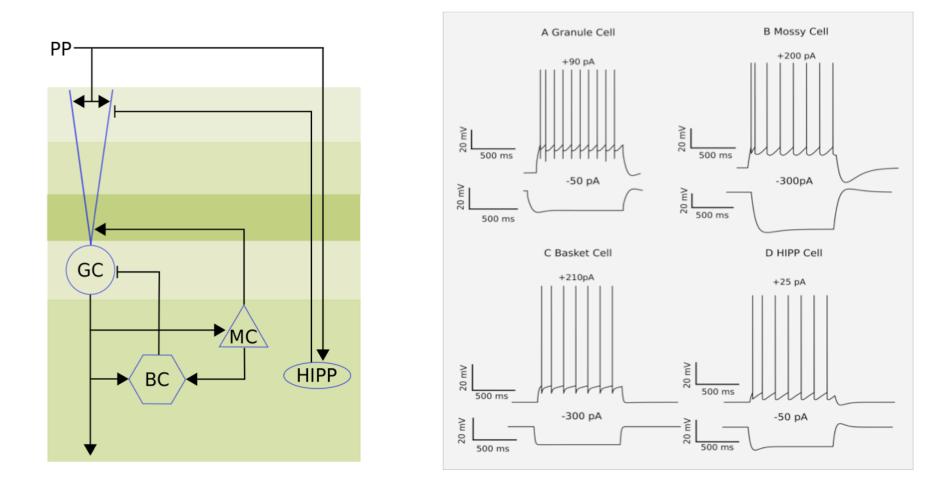

### Population overlap

• **Dentate Gyrus**: hippocampal subregion that accomplishes this task

### A simplified Dentate Gyrus network model

A simplified network model of the DG where Granule Cells are equipped with dendrites

Cell types are validated against experimental data

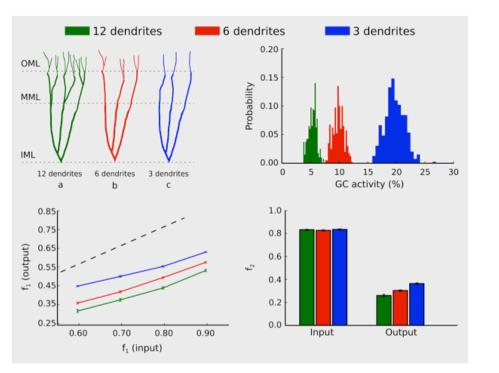

### DG dendrites aid pattern separation

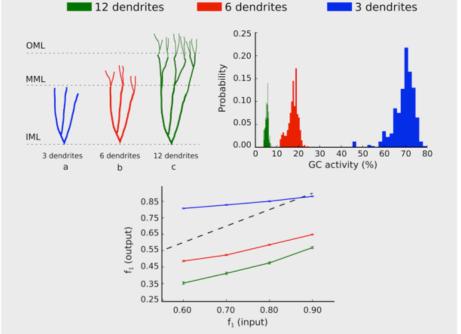

### **Dendritic ablation**

- GC models with 12, 6, 3 dendrites
- Same path length
- Same number of inputs

### Dendritic growth

- GC models with 3, 6 and 12 dendrites
- Different path length
- Same number of inputs

Pattern separation efficiency decreases with dendritic ablation; fewer dendrites  $\rightarrow$  worse performance.

#### Pattern separation efficiency increases with dendritic growth; More, longer dendrites $\rightarrow$ better performance.

Chavlis et al, Hippocampus, 2016

### Learning associative memories

Memory associations for the word "fly"

Fear/context memory associations in mice

# TRAINING

Animal is placed in novel context
 Hears a tone
 Receives foot shock

### CONTEXTUAL TEST

Animal is returned to same context
 Test for freezing behavior

### CUED TEST

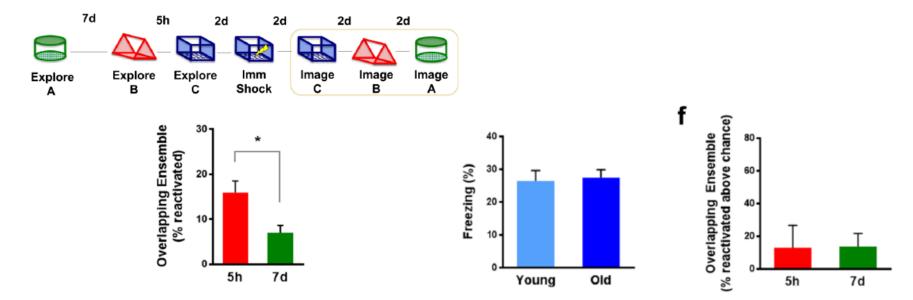

Animal is placed in modified context
 Hears a tone

Test for freezing behavior

## Network level: associating memories via neuronal overlaps

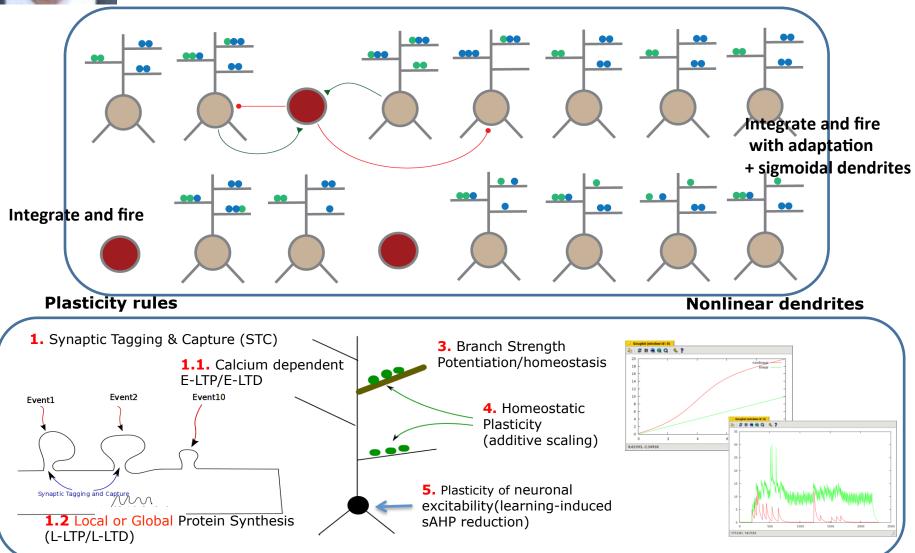

New findings (Cai, et al, Nature, 2016) show that two memories are linked if learned within a few hours, due to **overlapping storage in common** neurons. This ability declines with age.

**George Kastellakis** 

### Associative memory network model

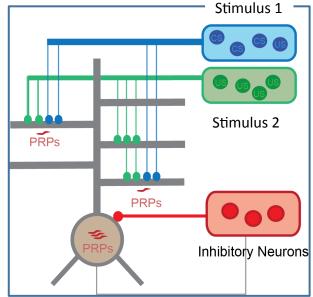

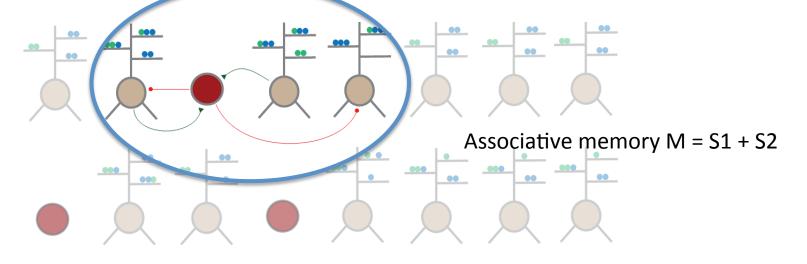

### Associative memory encoding in the model

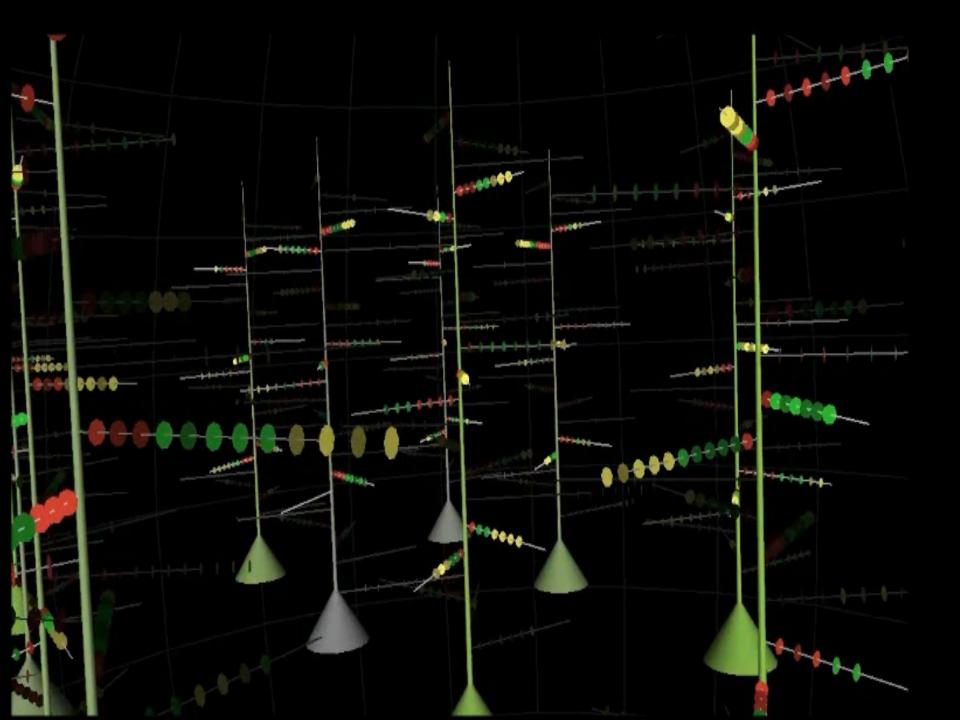

**Presentation:** Each stimulus is represented by a set of afferent axons which initially target 70% of the neurons of the (naïve) network at randomly selected dendrites.

**Learning:** Each stimulus (1s, 30 Hz Poisson train) is presented repeatedly to the network (for 4s) and plasticity (synaptic LTP/LTD, branch strength potentiation) takes place. Homeostatic mechanisms & plasticity of intrinsic excitability operate after learning.

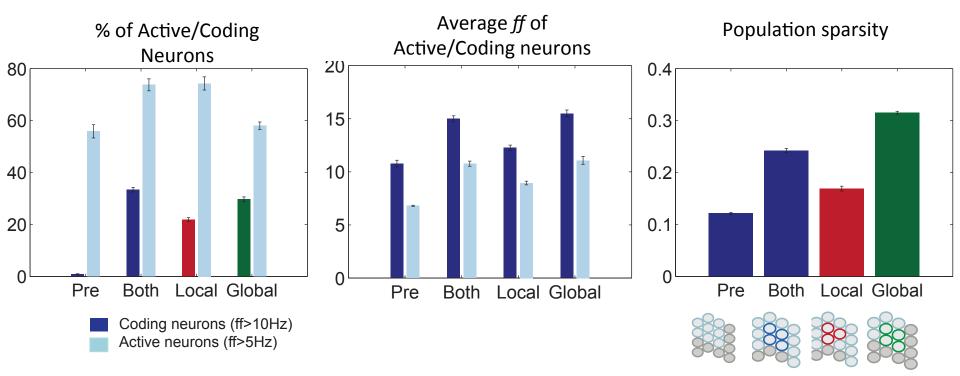

**Recall:** By presenting S1 or S2 we recall the memory (S1+S2), we identify the neuronal population that is "recruited" by the memory and we characterize its properties.

### Encoding a single associative memory

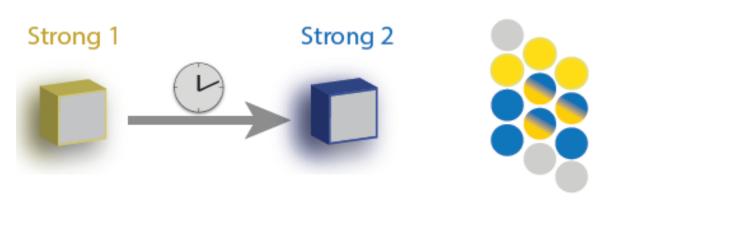

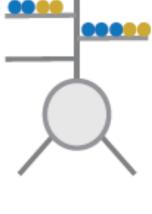

Successful encoding of a (S1+S2) pair leads to **20-30% of coding neurons** (*ff* >10Hz upon presentation of either S1 or S2)

The average ff of these neurons is 10-15 Hz

The network response after learning is **much sparser** than before, especially under Global PRP conditions

### **Encoding two strong memories**

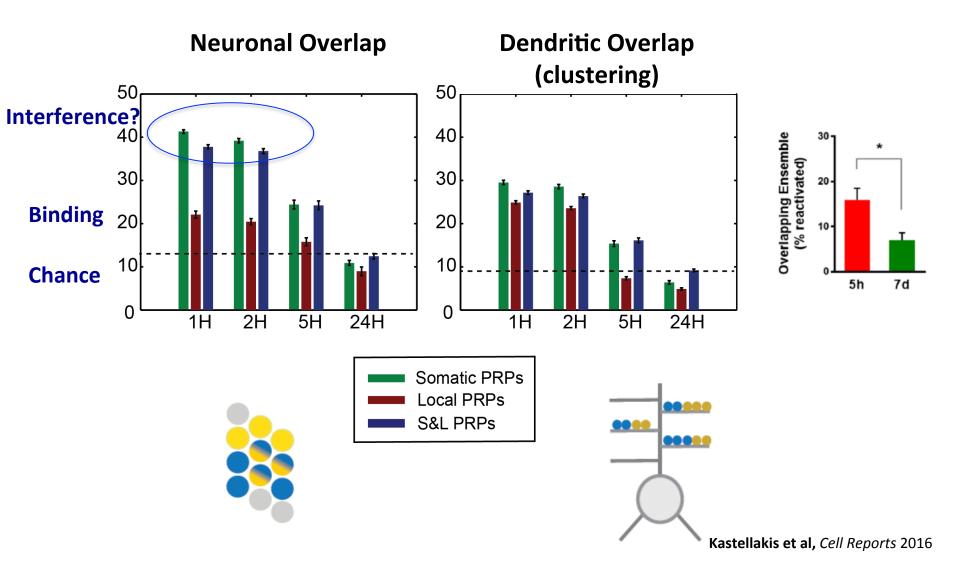

Two memories separated by several hours

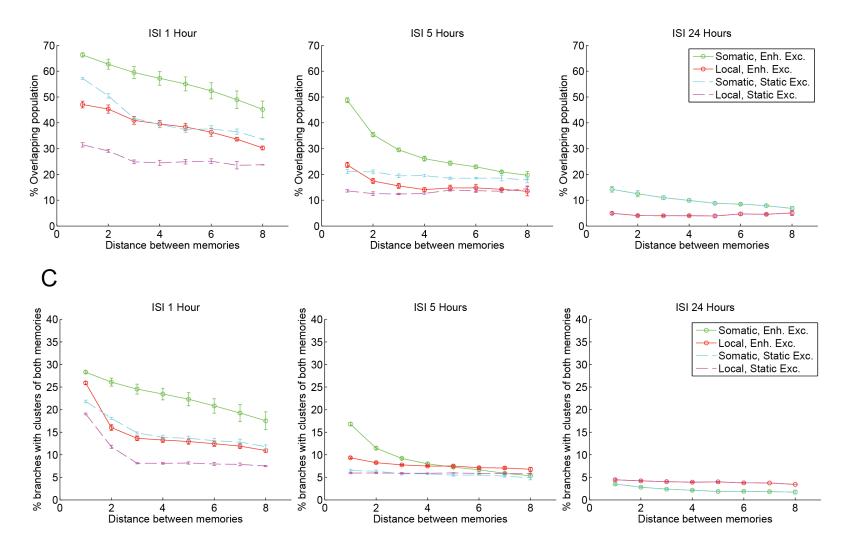

Neuronal Overlap neurons coding for both memories **Dendritic Overlap** branches with potentiated synapses from both memories

Strong memory encoding leads to increased neuronal excitability of the encoding neurons. The increase lasts for 12 hours

## **Encoding two memories**

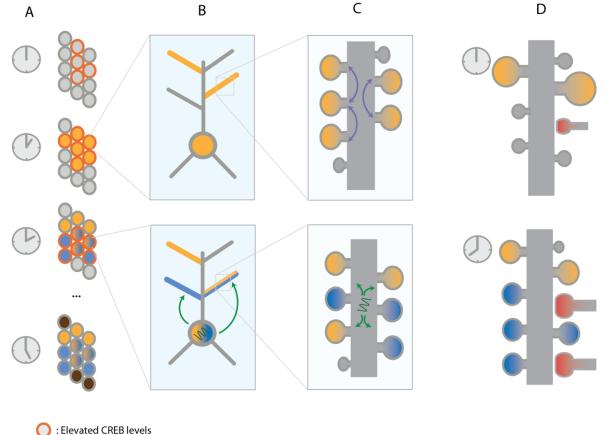

## Linking multiple memories across time

Prediction: memories are linked through neuronal and dendritic overlaps. Extend of linking depends on the mode of PRP synthesis/availability.

# Linking memories via synapse clustering

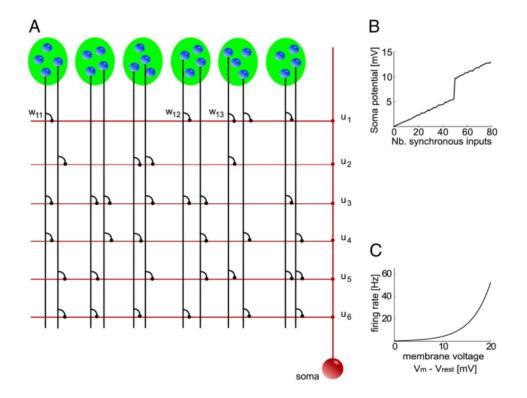

- Plasticity-related proteins
  - : Crosstalk / cooperative plasticity
  - : Inhibitory inputs

### Branch-Specific Plasticity Enables Self-Organization of Nonlinear Computation in Single Neurons

Soma response  

$$v(t) = V_{\text{rest}} + \sum_{k=1}^{\infty} u^{\text{passive}} p_k(t) + u_k a_k(t),$$

<sup>upassive</sup>: Passive component  $u_k$ : coupling strength  $a_k$ : active component (dend. spike)

Inputs in nonlinear dendrites with plastic coupling strengths

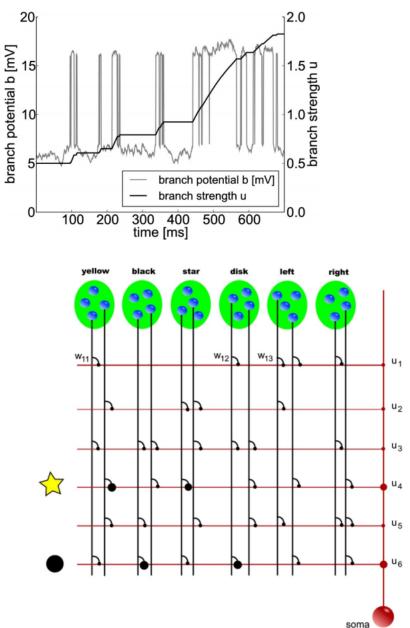

Legenstein, J.Neurosci 2011

## Feature binding in active dendrites

Dendritic spikes increase dendriticsomatic coupling strength

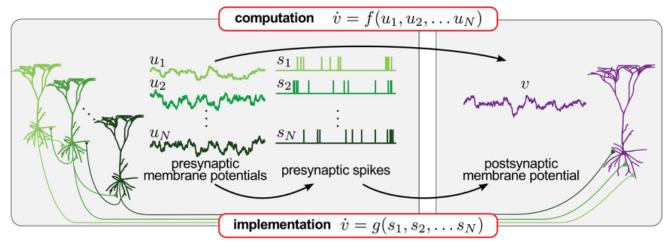

This is coupled with an STDP rule that is dependent on the depolarization of the dendritic branch

Together these allow each dendrite to discriminate a specific combination of input characteristics (binding), for example 'yellow star' and 'black circle'

### Dendritic nonlinearities are tuned for efficient spike-based computations

Neurons optimize the transformation of presynaptic potentials to postsynaptic u via f

However this function is implemented in neuronal harware through presynaptic spikes via *g* 

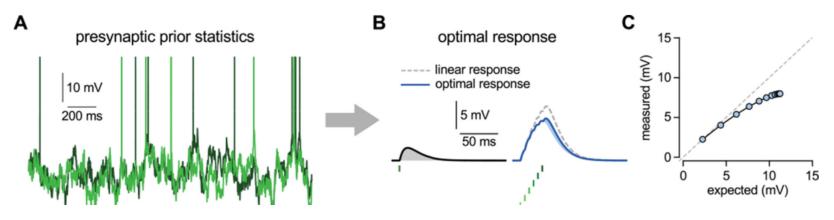

The authors sought to identify the properties that dendrites must have so that the computation is optimal i.e.  $f(u1,u2...) \approx g(s1,s2...)$ 

Assuming a simple nonlinear dendritic response model

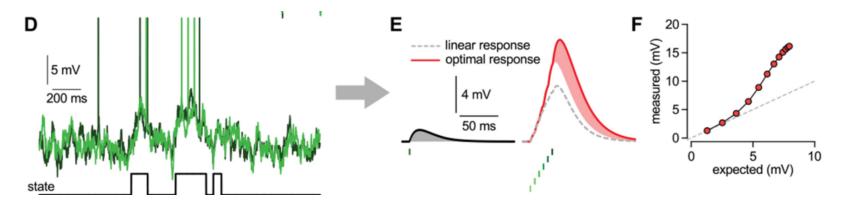

$$\begin{aligned} v_{\text{den}}(t) &= v_{\min} + (v_{\max} - v_{\min}) \frac{1}{1 + e^{-v_{\text{lin}}(t)}} \\ \dot{v}_{\text{lin}} &= -\mathscr{A}v_{\text{lin}} + \mathscr{B}s(t) - \mathscr{C} \end{aligned}$$

Ujfalussy, eLife 2015

- The authors use their model to predict the optimal response of dendrites to realistic inputs from other neurons.
  - When inputs are uncorrelated, the optimal response is linear (averaging)

- When inputs are correlated, the optimal response is nonlinear.

Ujfalussy, eLife 2015

## Summary

- Prediction: dendrites of various cells integrate inputs as semiindependent sigmoidal units. Verified
- Prediction: sigmoidal dendritic integration increases storage capacity
- Prediction: The dendrites of DG cells contribute to pattern separation by enhancing sparsity. Pending
- Prediction: memories are linked through neuronal and dendritic overlaps. Verified Extend of linking depends on the mode of PRP synthesis/availability. Pending
- Prediction: sigmoidal dendrites become tuned to recognize associated information. Pending
- Prediction: active dendrites are tuned to implement spike-based computations. Explains data
